1 Management summary

1.1 General project introduction
The infrastructural investment “Sewerage and Wastewater Treatment Plants of City of Poreč”– Project Poreč, co-funded by European Union, is one of the largest investments in the public sector in Republic of Croatia. It involves rehabilitation and extension of the existing sewerage system and construction of four new wastewater treatment plants (WWTPs). The goal is to better protect the environment in and around the Poreč coastal area. Complementary a project is developed titled “Integrated Modelling of Wastewater Infrastructure System of City of Poreč” – Modelling Project. This project is an integrated environmental assessment to obtain a better understanding of the environmental impact of the system performance which is evaluated under range of operational conditions. A scenario study is developed using state-of-the-art (modelling) tools and methods which allows a holistic assessment of the wastewater system. The results of this study are in assistance of future operations and wastewater management in the region and used to elevate knowledge and professional skills of local water sector professionals.

The Modelling Project consists of 4 main components, namely:
- Part 1: Modelling the sewage collecting and transport system of City of Poreč,
- Part 2: Modelling of operation and performance of 4 WWTPs of City of Poreč,
- Part 3: Model assessment impact offshore outlets on aquatic water quality,
- Part 4: Establishment of the experimental laboratory setup for monitoring and optimization of wastewater management and operation.

Including a training is organized to extend the capacity of water professionals in the use of wastewater modelling for future assessments.

The Modelling project has a holistic system approach covering collection, processing, and aquatic discharge of wastewater, the interrelation between the different wastewater systems and impact on the environment, public health, and coastal seawater quality.

Several scenarios are calculated to explore the impact of Project Poreč on the previous mentioned factors and to and establish the best methods for management of the wastewater systems from an integrated perspective.

Modelling is used to demonstrate how upgrade of the Poreč wastewater system improves the environment. Further insight is developed in the overall interaction of the sub-systems on seawater quality. Knowledge is developed on how to operate and optimize the different wastewater systems, with the best overall results.
1.2 Project goals
The overall objective of the Poreč modelling project is to demonstrate how upgrading the total wastewater system improves the sea water quality in the Poreč coastal region. Therefore, the total wastewater system is modelled consisting of several sub-systems. By modelling the WWTP under different (extreme) conditions it is investigated how effluent discharge load and quality will affect the sea water quality. For each studied scenario, effluent concentration and flow profiles are calculated. These data are subsequently used as input for sea water quality modelling from which the environmental impact is calculated.

1.3 Context of this report
This report belongs to the reports in the series “modelling project part 2: Modelling of operation and performance of 4 WWTPs of City of Poreč”. Each WWTP is modelled and reported in a series of 4 documents of which this is the final. For accessibility the reports are set up using identical format and methods. Modelling project Part 2 is developed in four steps:

- Step 1: Static WWTP modeling using detailed design data. In the total project this is report number 5 consisting of 4 sub-reports, one for each WWTP (report number 5.1 to 5.4).
- Step 2: Dynamic WWTP modeling based on dynamic winter and summer influent measurements (data 2019). In the total project this is report number 6, consisting of 4 sub-reports, one for each WWTP (report number 6.1 to 6.4).
- Step 3: Analysis of operational WWTP scenarios up to the year 2045. In this step a series of operational scenarios are developed, and the potential coastal discharge loads and concentrations are quantified based on extrapolation simulations. In the total project this is report number 7, consisting of 4 sub-reports, one for each WWTP (report number 7.1 to 7.4).
- Step 4 (this report series): Model calibration and validation based on new operational measurements done in 2022. The model validity is tested by reproducing a new influent and effluent data set without the need of significant model adjustments. In the total project this is report number 8, consisting of 4 sub-reports one for each WWTP (report number 8.1 to 8.4).

1.4 Background and previous investigations
This research is part of an integrated environmental assessment of the wastewater transport, collecting and treatment system including the coastal recipient. The goal of this research is to obtain a better understanding of the environmental impact of modernization of the City of Poreč wastewater system and its performance. This report is part of a series studying the operation of 4 wastewater treatment plants of the larger City of Poreč. Models of the wastewater treatment are developed from detailed design information and influent flow and concentration data are measured in the summer and winter of 2019 and winter of 2022. In previous reports (numbered report 5, 6 and 7) model evaluations have been performed simulating a range of operational conditions and future scenarios. In report number 5 the average performance is evaluated using a static model. In report number 6
models are further developed to test and evaluate operation under realistic dynamic conditions. In report number 7 models are projected towards winter and summer conditions in 2045 including a dynamic scenario with peak loading and rain event. Based on the simulations results, the impact of the upgraded wastewater facilities on the coastal seawater quality is assessed. In this report the validity of the previously developed models is further investigated by calibrating the model using a new dataset measured in 2022, including operational performance data. It is tested if the previously developed dynamic model can reproduce measured effluent quality without having to alter critical model parameters. The study adds to the overall validity of the previously performed model calculations and scenario projections.

1.5 Reader
This report presents the validation of the previously developed model. Therefore, a static calibration is performed using a new 2022 operational dataset with influent and effluent measurements. The calibration methodology is according to published literature and explained in report 5 of this series. The setup and calibration of the dynamic model is explained in report 6. It was concluded that the model required little parameter adjustments, all not critical and well within the advised settings (default BioWin). In report 7 the model is used for scenario calculations towards the year 2045. This report tests the assumptions for the parameter settings and validates its application. The model settings are validated by calibrating the model using a new operational dataset with influent and effluent data measured in the winter of 2022. In chapter 3 the 2022 measured flow data is evaluated and presented for model application. In chapter 4 the influent quality sampling (concentrations) is discussed, and measurement results are presented and prepared for model application (appendix 1). Chapter 5 presents the influent (mass) loading profiles (appendix 2). Chapter 6 discusses the influent characterization results (appendix 3). Chapter 7 presents the model calibration and validation (appendix 4 and 5). Measured 2022 effluent results are compared with results of the calibrated model. The model is determined to be valid when effluent values are reproduced without significant adjustment of (stoichiometric) parameters. For all model studies some finetuning is necessary to reproduce specific operational conditions. For example, mixing conditions or aeration controller settings. Therefore, some kinetic parameters are adjusted within a typical range.

1.6 General conclusions
- The model is tested successfully on an independent data set and reproduced all data without significant adjustments.
- The model is tested reliable and validated for use for operational and scenario evaluation.
- The above conclusions apply to all presented results, under which previous WWTP modelling reports published in this series, which have used the validated model.

1.7 Recommendations
It is recommended to proceed with final development of the scenario analysis and seawater modelling taking in account the presented conclusions.
2 Introduction

2.1 Context of this report
This report belongs to the reports in the series “modelling project part 2: Modelling of operation and performance of 4 WWTPs of City of Poreč”. Each WWTP is modelled and reported in a series of 4 documents of which this is the final. For accessibility the reports are set up using identical format and methods. Modelling project Part 2 is developed in four steps:

- **Step 1**: Static WWTP modelling using detailed design data. In the total project this is report number 5 consisting of 4 sub-reports, one for each WWTP (report number 5.1 to 5.4).
- **Step 2**: Dynamic WWTP modelling based on dynamic winter and summer influent measurements (data 2019). In the total project this is report number 6, consisting of 4 sub-reports, one for each WWTP (report number 6.1 to 6.4).
- **Step 3**: Analysis of operational WWTP scenarios up to the year 2045. In this step a series of operational scenarios are developed, and the potential coastal discharge loads and concentrations are quantified based on extrapolation simulations. In the total project this is report number 7, consisting of 4 sub-reports, one for each WWTP (report number 7.1 to 7.4).
- **Step 4** (this report series): Model calibration and validation based on new operational measurements done in 2022. The model validity is tested by reproducing a new influent and effluent data set without the need of significant model adjustments. In the total project this is report number 8, consisting of 4 sub-reports one for each WWTP (report number 8.1 to 8.4).

2.2 Background and previous investigations
This research is part of an integrated environmental assessment of the wastewater transport, collecting and treatment system including the coastal recipient. The goal of this research is to obtain a better understanding of the environmental impact of modernization of the City of Poreč wastewater system and its performance. This report is part of a series studying the operation of 4 wastewater treatment plants of the larger City of Poreč. Models of the wastewater treatment are developed from detailed design information and influent flow and concentration data are measured in the summer and winter of 2019 and winter of 2022. In previous reports (numbered report 5, 6 and 7) model evaluations have been performed simulating a range of operational conditions and future scenarios. In report number 5 the average performance is evaluated using a static model. In report number 6 models are further developed to test and evaluate operation under realistic dynamic conditions. In report number 7 models are projected towards winter and summer conditions.
in 2045 including a dynamic scenario with peak loading and rain event. Based on the simulations results, the impact of the upgraded wastewater facilities on the coastal seawater quality is assessed. In this report the validity of the previously developed models is further investigated by calibrating the model using a new dataset measured in 2022, including operational performance data. It is tested if the previously developed dynamic model can reproduce measured effluent quality without having to alter critical model parameters. The study adds to the overall validity of the previously performed model calculations and scenario projections.

2.3 Reader
This report presents the validation of the previously developed model. Therefore, a static calibration is performed using a new 2022 operational dataset with influent and effluent measurements. The calibration methodology is according to published literature and explained in report 5 of this series. The setup and calibration of the dynamic model is explained in report 6. It was concluded that the model required little parameter adjustments, all not critical and well within the advised settings (default BioWin). In report 7 the model is used for scenario calculations towards the year 2045. This report tests the assumptions for the parameter settings and validates its application. The model settings are validated by calibrating the model using a new operational dataset with influent and effluent data measured in the winter of 2022. In chapter 3 the 2022 measured flow data is evaluated and presented for model application. In chapter 4 the influent quality sampling (concentrations) is discussed, and measurement results are presented and prepared for model application (appendix 1). Chapter 5 presents the influent (mass) loading profiles (appendix 2). Chapter 6 discusses the influent characterization results (appendix 3). Chapter 7 presents the model calibration and validation (appendix 4 and 5). Measured 2022 effluent results are compared with results of the calibrated model. The model is determined to be valid when effluent values are reproduced without significant adjustment of (stoichiometric) parameters. For all model studies some finetuning is necessary to reproduce specific operational conditions. For example, mixing conditions or aeration controller settings. Therefore, some kinetic parameters are adjusted within a typical range.
3 Influent flow measurements

3.1 Introduction and methods
The influent flow is measured for 24-hours (1 day) with measurement points produced every 2 hours based on a collected flow sample for all 4 treatment locations. The measurement period for WWTP Poreč-South and WWRP Vrsar starts Monday 17-01-2022 at 9:00 and for WWTP Poreč-North and WWRP Lanterna starts Tuesday 18-01-2022 at 9:00. The measurement day was with dry weather. There are no missing datapoints and the measured did not require data to be reconstructed. From the measured flow profile an hourly average flow is calculated for each hour of the day. The profile is used as an input for dynamic modeling.

3.2 Winter influent flow measurement results

![Winter 2022 - Average Wastewater Flow per WWTP](image)

**Figure 1.** Winter 2022 - Average Dry Weather Wastewater Flow per WWTP.
Figure 2. Winter 2022 - Surface plot of the total combined wastewater flow. The order of WWTP’s is from lowest to highest wastewater producing community.

Figure 3. Winter 2022 - Total (sum of WWTP’s) of the wastewater flow per hour.
**Figure 4.** Winter 2022 - WWTP Poreč-South Dry Weather Wastewater Flow 24-hour average hourly measurements.

**Figure 5.** Winter 2022 - BioWin modelling WWTP Poreč-South: Wastewater Flow measured 24-hours and repeated for 7-days used for dynamic model input. The data is interpolated in the model on an hourly basis.

### 3.3 Conclusions flow measurements

Influent dry weather flow data measured in the winter of 2019 and 2022 are comparable. There is similarity in the minimum and maximum flow data as well as the flow distribution pattern over the day on an hourly basis. The profile is used in the calibration study to validate the model performance.
4  Influent quality sampling

4.1  Sampling method
Raw sewage wastewater is sampled at 4 WWTP locations; WWTP Poreč-North, WWTP Poreč-South, WWRP Vrsar and WWTP Lanterna. Continuous 24-hour automated samplers are used for a continued period of 24 hours. Per WWTP approximately 180 samples are collected and analyzed. Some by on-line measurement. The measurement period for WWTP Poreč-South and WWRP Vrsar starts Monday 17-01-2022 at 9:00 and for WWTP Poreč-North and WWTP Lanterna starts Tuesday 18-01-2022 at 9:00. During the measurement period there was absence of rain.

The type of wastewater sampler used is Hach AS950 Portable Sampler and WaterSam Ports. Samples are taken every 9-30 minutes (flow proportional) in bottles of volume 550–800 mL which are rotated automatically every 2 hours, for 24 h (total of 12 vessels collected per 24 hours for each sampling location). After a day of operation, samples are taken to the laboratory for analysis (Zagreb Laboratory for Water Technology at the Faculty of Food Technology and Biotechnology). Samplers are thermally insulated and refrigerated to preserve the samples and reduce occurring reactions.

4.2  Measurement adjustments in the raw data
For the influent data some datapoints are corrected. All measured influent TSS measurements are too high in relation to the measurements of BOD and COD in the same samples. Measurement errors in TSS typically are the result of non-homogeneous samples. Especially the larger heavier TSS fraction will settle if the mixing conditions in a sewage sampling point are not ideal. COD is less affected because COD is related to the smaller
and lighter particulate (colloidal) fraction that will settle less rapidly and therefore less susceptible for poor mixing conditions. To compensate for the overestimation of measured solids all TSS measurements are reduced by 29% brining the measurements within more typical concentration range and ratio’s relative to BOD and COD. VSS is calculated from TSS and ISS measurements and therefore adjusted simultaneously.

4.3 Calculation method for the average influent concentration

For each 2-hour composite sample the flow volume is measured and concentration measured of all parameters in table 1. From these data every 2 hours the influent loads are calculated for each parameter. From the load profile the flow proportional (weighed) influent concentrations are calculated. Only weighed concentration are used in the model calculations. The results are presented in the following graphs.

![Graph showing winter 2022 flow-weighted average influent concentrations per WWTP.](image)

Figure 6. Winter 2022 - Flow-weighed average influent concentrations per WWTP.

4.4 Influent concentration profiles

The concentration of wastewater varies over time due to all kind of disturbances but most important population behavior. Human regular activity results in a distinctive measurement profile. For each measured parameter daily profiles are calculated and presented in the figures below. Measured concentration peaks are related to the sewage flow. High flow results in short sewer residence time and high concentration peaks early in the day while low flow results in lower peaks occurring later in the day. Transport of particulate material is very much dependent on the flow velocity in the sewer system. During the winter low flow season, it takes longer before particulate material arrives at the WWTP. This material settles overnight in the sewer and is collected in the morning when the flow increases.
Ammonia and orthophosphate peaks in the morning as the result of human source urine. The time on which peaks are measured at the WWTP starting from 6 hours in the morning, indicates the residence time in the sewer system. This effect is observed from the data in the figures below.

4.5 COD Influent concentration - Winter 2022

Figure 7. Winter 2022 - 24-hour COD Influent Concentration profile per WWTP.

Figure 8. Winter 2022 - WWTP Poreč-South 24-hour average COD and COD micro-filtered influent Concentration.
Figure 9. Dynamic Simulation – WWTP Poreč-South – Winter 24-hour average COD, COD micro-filtered, COD particulate, BOD and BOD filtered influent concentration. One day of measurement is repeated for 7 days in the dynamic simulation. The model input is the measured total COD concentration. Other fractions are calculated from the influent specification.

4.6 Nitrogen influent concentration – Winter 2022

Figure 10. Winter 2022 - 24-hour TN Influent Concentration profile per WWTP.
Figure 11. Winter 2022 - WWTP Poreč-South 24-hour average TN and NH4 influent Concentration.

Figure 12. Dynamic Simulation – WWTP Poreč-South – Winter 24-hour average TKN, NH4 and particulate TKN influent concentration. One day of measurement is repeated for 7 days in the dynamic simulation. The model input is the measured TKN concentration. The other fractions are determined from the influent specification.
4.7 Phosphorus influent concentration – Winter 2022

Figure 13. Winter 2022 - 24-hour TP influent concentration profile per WWTP.

Figure 14. Winter 2022 - WWTP Poreč-South 24-hour average TP and PO4 influent concentration.
Figure 15. Dynamic Simulation – WWTP Poreč-South – Winter 24-hour average TP and PO4 influent Concentration. The model input is the measured TP concentration. One day of measurement is repeated for 7 days in the dynamic simulation. PO4 is determined from the influent specification.

4.8 Total Suspended Solids influent concentration – Winter 2022

Figure 16. Winter 2022 - 24-hour TSS influent concentration profile per WWTP.
**Figure 17.** Winter 2022 - WWTP Poreč-South 24-hour average TSS, VSS and ISS influent concentration.

**Figure 18.** Dynamic Simulation – WWTP Poreč-South – Winter 24-hour average TSS, VSS (organic particulate) and ISS (inorganic particulate) influent concentration. One day of measurement is repeated for 7 days in the dynamic simulation. The model input is the measured ISS concentration. VSS is calculated based on (constant) fractions determined in the influent specification. TSS is modelled as the sum of ISS and VSS.
4.9 pH influent measurements - Winter 2022

Figure 19. Winter 2022 - WWTP Poreč-South 24-hour average pH influent measurement.

Figure 20. Dynamic Simulation – WWTP Poreč-South – Winter 24-hour average influent pH measurement. pH is a dynamic model input. The alkalinity of wastewater is estimated as a constant obtained from Poreč drinking water quality.
5  Influent loading profiles

5.1  Average influent loads
Daily average influent loads are presented in the graph below. The scale (0-100%) represents the total influent (total Poreč area) and the relative influent fractions treated by each WWTP.

![Graph showing proportional share influent load per WWTP]

**Figure 21.** Winter 2022 - Proportional Share Influent Load per WWTP.

5.2  Influent COD 24-hour dynamic loading profile
The loading profile typically follows the flow profile with exception for periods where concentration peaks occur. The combined COD wastewater load for the Poreč area during the winter of 2022 is shown in the figures below. COD is partly particulate material and is transported more slowly through the sewer than soluble compounds. This is effect is increased at low flow conditions. Compared to TN, the morning COD peak typically is lower and has a more gradual loading pattern over the day. The measured COD loading profile is typical for domestic source.
5.3 Influent Nitrogen 24-hour dynamic loading profile

The total nitrogen (TN) loading is presented in the graphs below. The data shows a typical domestical source. A large fraction of TN is soluble ammonium which is easily transported in the sewer. This typically results in a high peak of ammonium in the morning between 11:00 and 13:00, depending on the flow and sewer residence time. Ammonium peaks result in a high oxygen demand at the WWTP because of the nitrification process. Under peak conditions, especially when the wastewater is warm, aeration can become limiting. Small presence of nitrate is measured in the sewage. Appearance of nitrate in closed sewers could be caused by nitrate rich groundwater infiltration.
5.4 Influent Phosphorus 24-hour dynamic loading profile
The phosphorus loading is presented in the graphs below. Phosphorus consists of a soluble ortho-phosphate fraction which is easily transported in the sewer system. Typically, a smaller fraction is related to particulate organic material (particulate COD). Orthophosphate originates mostly from domestic source in the form of urine. Phosphate often resembles the ammonium profile, peaking between 11:00 and 13:00.
Figure 26. Winter 2022 - Sum of all WWTP’s. Hourly average influent TP load based on 1 measurement day, dry weather conditions.

Figure 27. Winter 2022 - WWTP Poreč-South hourly average influent loads TP and PO4, based on 1 measurement day, dry weather conditions.

5.5 Influent Total Suspended Solids 24-hour dynamic loading profile
The loading of particulate material (total suspended solids) is presented in the graphs below. Particulate material typically has a longer transportation time in the sewer. Solid materials will settle in the sewer, especially during dry weather and low nighty flow. Therefore, at low flow conditions, TSS concentration measurements usually are underestimated by 15-25%. During peak flow or rain events, the settled TSS fraction is stirred up and transported to the WWTP. Under these conditions, concentration measurements are generally overestimated. As a result, during low season and low flow conditions, usually only one TSS peak is measured during the day, while during high
season two peaks are measured: One in the morning and one in the evening coinciding with the flow dynamics. TSS consists largely of organic material (volatile suspended solids or VSS). The inorganic fraction (ISS) is typically 6-9%. TSS is typically organic material from domestic source and solids collected from the pavement during rain events. Typically, half of the domestic TSS source is cellulose originating from toilet paper. Industrial and agricultural TSS usually are fibers with a low biodegradability.

**Figure 28.** Winter 2022 - Sum of all WWTP’s. Hourly average influent TSS load based on 1 measurement day, dry weather conditions.

**Figure 29.** Winter 2022 - WWTP Poreč-South hourly average influent loads TSS, VSS and ISS, based on 1 measurement day, dry weather conditions.
6 Influent specification model

6.1 Determining fractions of influent concentrations
Influent is evaluated based on the BioWin influent specification model, also called influent characterization. This model makes separate calculations to be used as an input for the BioWin activated sludge model. The model is presented in appendix 3. The BioWin influent specification model requires average influent measurement values as input and calculates a set of wastewater parameters presented in the table below. From total COD, N and P the model determines the fractions. For example, the fractions soluble, particulate, and colloidal, biodegradable, and inert and the nitrogen and phosphorus fractions of the different COD fractions. Note that all fractions in the table are in terms of COD. BioWin calculates the influent strength in terms of COD. BOD is fitted to the measured COD using the specification model presented in appendix 3.

Figure 30. BioWin specification of COD fractions based on total COD in the influent. Blue is soluble (S) and (olive) green particulate or colloidal particulate (X). Green lined boxes are biodegradable and black lined boxes inert. Yellow text indicates readily biodegradable and green text slowly biodegradable.
29

Table 2. BioWin default influent fractions and calibrated values based on 2022 influent data. Technical note: Setting fractions to zero may result in simulation difficulties.

6.2 Results of the specification model

The table above presents the results of the influent specification model. The parameters are input values for BioWin. Input data for pH, Ca, Mg, and alkalinity are used to calculate pH and chemical precipitation reactions. Estimates of Ca, Mg, and alkalinity are made based on data from local drinking water quality measurements provided by the drinking water company. The unbiodegradable soluble COD and TKN in the influent is estimated based on measurement of effluent soluble COD and TKN. For systems with an SRT larger than 3 days typically 98% of effluent soluble COD is unbiodegradable (Fus, SI). Glass Filtered COD (CODGF) is filtered over a glass fiber filter of 1,2 microns and typically is 40% of TCOD. Membrane Filtered COD (CODMF) is flocculated, and membrane filtered over 0,45 microns and thereby the fraction CODMF is always lower than CODGF which contains some colloidal (particulate) material. BOD measurements are including the nitrification inhibitor ATU (therefore carbonaceous BOD). Volatile fatty acids are typically assumed to be 100% acetate. However also a smaller fraction of propionate may be present in raw sewage.

6.3 Conclusions

The measured influent data results in a well fitted specification model within acceptable range of parameter settings. Influent data is tested reliable and validated as wastewater of mainly domestic source applicable for WWTP modelling. The result of the specification model is a set of BioWin model input parameters and is part of the model calibration procedure which is further discussed in the following chapter. The specification model and calculation method are presented in appendix 3.
7 Model calibration and validation

7.1 Static calibration
The model is calibrated based on average 24-hour dynamic winter 2022 influent and effluent measurements. Model parameters are adjusted to reproduce the measured average effluent performance of COD, N and P. The parameter adjustments for calibration are presented in the table below. No stoichiometric parameters are adjusted. This indicates the model is valid. Some kinetic parameters are adjusted to finetune the model performance on the specific dataset and correct for approximations used in the simulation of operational conditions. Finetuning of kinetic parameters is allowed within acceptable margin and typically required for each new simulated condition.

7.2 Parameters PAO updated to TUDP-model
In BioWin the parameter for Anoxic P/PHA uptake and P/Ac release ratio are updated to the published TUDP-model. It is found that the anoxic performance of PAO’s is less conservative than assumed in the default BioWin parameter settings. The PAO parameters are updated according to the latest research.

7.3 Anoxic growth factors for OHO and PAO
This parameter represents the fraction of heterotrophic organisms that can grow under both aerobic and anoxic conditions. The parameter proportionally reduces the growth rate under anoxic conditions. Substrate and nutrient limitations may further reduce the growth rate. Anoxic growth factors are adjusted to fit the model on the measured denitrification and effluent nitrogen concentration. The growth factors typically are increased for WWTP’s designed with pre-denitrification where biomass is adapted to grow under full anoxic
conditions (this in contrary to simultaneous nitrification and denitrification often observed in carousel type processes). By increasing the growth factor, a larger fraction of heterotrophic biomass (PAO and OHO) will have denitrifying capacity. In systems without pre-denitrification these factors are usually set to the lower (default) value. The applied model adjustments are well within the acceptable range and do not affect the model reliability. These parameters also can change because of operation (e.g., applied anoxic recycle flow rate).

7.4 DO half saturation
The DO half saturation is a kinetic parameter determining the sensitivity for oxygen. It is adjusted to compensate for partial unaerated zones or unaerated periods which are the result of the oxygen control settings. By increasing the DO half saturation for denitrification, more simultaneous nitrification and denitrification (SND) will occur under low DO conditions. The parameter adjustment simulates the effect of partial aerated tanks. Under normal settings nitrite (NO2) is formed in the model. Most likely as result of the simplified oxygen modeling because no nitrate is measured in the effluent. To compensate for this, the DO half saturation for nitrification is decreased to finetune the formation of nitrite. This has no significant effect on the model reliability and is mainly applied for fine tuning effluent results. The DO half saturation for nitrification is increased to reduce the nitrification rate at low DO concentration. This is done to reproduce the higher measured effluent ammonium concentration. Bacteria adjust to the operated DO conditions. This parameter therefore will change during operation and needs fine tuning for each simulated period. It is also possible the system is still adapting its kinetic sensitivity after its start-up and therefore not (yet) in steady state.

7.5 Particulate influent COD/VSS ratio
These parameters are the result of the influent specification calculation (appendix 3). The COD/VSS ratio determines how much solids accumulate in the WWTP and how much is biodegraded. The adjustments are directly derived from the applied influent measurements and well within the acceptable range and do not affect the model reliability.

7.6 Calibration results and discussion

In the table below, the results of the model and the effluent measurements are compared. The model predicts the effluent within a reasonable range. In the calibration procedure the model is fitted primarily to NH4 by adjusting the aeration control, and it is attempted to find the most optimal overall dynamic fit with the least parameter adjustment required. There are however some small deviations between the measurements and model results which are here discussed. Typically, measurements have a margin of error and show a spread as the result of small errors. However, measured and modelled effluent BOD shows a consistent deviation and is not predicted accurately. In general BOD is not a very reliable measurement especially in the low concentration range. Moreover, high soluble BOD in the effluent is unlikely for systems with sufficient aerobic SRT, which is the case for this WWTP (table 9). Therefore, it is assumed the measured BOD is overestimated (and consequently also total COD). Or the sample may be contaminated. The concentration values of NH4, NO3 and NO2 are reasonably predicted taking in account these concentrations vary depending on the operation and time of day. Effluent NH4, NO3 and NO2 are strongly dependent on the applied aeration and recirculation controls. Operational data was not available, and these controls are estimated in the model. This may also explain the (slight) formation of NO2 in the model which also is consistently overestimated compared to the measurements, which generally are zero. Most likely NO2 is not measured accurately for it is complicated to preserve and store samples properly and NO2 quickly can convert before being measured. Considering the relatively high measured NH4 some NO2 is expected to be formed. This is supported by TN which does not add up with other measured nitrogen components. This may indicate a measurement error. As the result of a model artifact TN in the model is underestimated; Filtered COD has no individual parameter to set the nitrogen fraction. In the MBR filtered COD is the only effluent COD fraction and this also partly can explain the (small) gap between measured and modeled TN.

**Figure 31.** Winter 2022 – WWTP Poreč-South – Model validation based on 24-hour dynamic effluent COD and BOD data. For all measured effluent results the model underpredicts measured effluent BOD. Typical effluent BOD for systems operated at SRT > 3 days BOD is below 3 mg/L. The BOD measurements are likely unreliable.
Figure 32. Winter 2022 – WWTP Poreč-South – Model validation based on 24-hour dynamic effluent TN, NH4 and NO3 data. The model is fitted to the effluent NH4 concentration. In the model 100% of effluent is buffered in the storage tank and measured variation in effluent TN cannot be simulated.

7.7 Model validation

The model is validated based on the presented calibration results; No stoichiometric or other critical parameters are adjusted to reproduce measured conditions. This indicates the model is valid and suited to simulate (dynamic) operational conditions and valid to be used for extrapolation to (future) load conditions (as is done in report 6 and 7). Validation is supported by dynamic model results. In the figures above the dynamic effluent performance is plotted against the measurements. The effluent is measured coming from the effluent buffer and is reasonably well reproduced by the model.

Figure 33. Winter 2022 – WWTP Poreč-South – Model validation based on 24-hour dynamic effluent TP.
7.8 Conclusion dynamic simulations
The WWTP result of the 2022 calibrated model (appendix 4) is largely identical to the results of the 2019 7-day dynamic winter simulation presented in report 7. The effluent concentration is simulated within the projected effluent limits. Due to operational differences of aeration, SRT, and internal recycles, operational hour to hour effluent results can differ considerably. However, the overall performance of COD, N and P-removal is largely identical for both the 2019 and 2022 models. This is explained by the minor parameter adjustments required to simulate both conditions. This indicates the model is well developed, has no gross shortcomings, and is tested valid for application in this research project.

7.9 Conclusions
- The model is calibrated based on the provided operational data.
- Parameters are all adjusted within the typical and acceptable range.
- No stoichiometric parameters are adjusted.
- All adjustments are used to fit the model to specific operational conditions and typically required for each performed simulation study.
- Based on the presented calibration results the model is validated for interpolation to study operational dynamics and extrapolation for scenario analysis.
- Additional validation is provided by the dynamic simulation.
- The 2019 and 2022 calibrated model results are in accordance.
- The model is tested valid for use in this research project.
8 Conclusions and recommendations

8.1 General conclusions
- The model is tested successfully on an independent data set and reproduced all data without significant adjustments.
- The model is tested reliable and validated for use for operational and scenario evaluation.
- The above conclusions apply to all presented results, under which previous WWTP modelling reports published in this series, which have used the here validated model.

8.2 Summary of technical conclusions
- Influent dry weather flow data measured in the winter of 2019 and 2022 are comparable.
- There is similarity in the minimum and maximum flow data as well as the flow distribution pattern over the day on an hourly basis.
- The measured profile is successfully used in the calibration study to validate the model performance.
- The measured influent data results in a well fitted model within acceptable range of parameter settings.
- Some measurements are inconsistent and corrected based on typical influent fractions.
- The total influent data set is tested reliable and validated as wastewater of mainly domestic source useful for WWTP modelling.
- The result of the specification model is used in the model calibration procedure.
- The model is calibrated based on the provided operational data.
- Parameters are all adjusted within the typical and acceptable range.
- No stoichiometric parameters needed to be adjusted.
- All adjustments are used to fit the model to specific operational conditions and typically required for each performed simulation study.
- Based on the calibration results the model is validated for interpolation, to study operational dynamics and for extrapolation and future scenario analysis.
- Additional model validation is provided by dynamic simulations.
- The 2019 and 2022 calibrated model results are in accordance.
- The model is tested valid for use in this research project.

8.3 Recommendations
It is recommended to proceed with final development of the scenario analysis and sea water modelling taking in account the presented conclusions.

Presenting the BioWin influent specification model

The influent is divided in its fractions and used in the BioWin model calculations. Therefore, several influent fractions are introduced to facilitate the calculations in the model (Table 27, BW-influent tab). An overview of the fractions is presented below including relation to actual analytical measurements.

The influent unbiodegradable COD (SUS) for systems with a SRT > 3 days is based on the effluent measurement of soluble (glass filtered) COD according to:

\[ S_{US} = COD_{S,EFF} = COD_{GF,EFF} \]  
(Eq. 1)

The fraction unbiodegradable COD is calculated according to:

\[ F_{US} = \frac{S_{US}}{TCOD} = \frac{COD_{GF,EFF}}{TCOD_{INF}} \]  
(Eq. 2)

Soluble COD is including the colloidal and expressed as CODS as the sum of all soluble model fractions. It can be measured from glass filtered COD according to:

\[ COD_S = S_{BSA} + S_{BSP} + S_{BSC} + X_{SC} + S_{US} = COD_{GF,INF} \]  
(Eq. 3)

Particulate (non-colloidal) COD (CODp or CODX) is the sum of particulate (non-colloidal) COD, particulate unbiodegradable COD and active biomass in the influent (XBH is often assumed zero) given by:

\[ COD_X = X_{SP} + S_{UP} + X_{BH} \approx X_{SP} + S_{UP} \]  
(Eq. 4)

CODX is calculated by subtracting the total COD and the soluble COD (CODS) which is calculated based on the glass filtered COD according to:

\[ COD_X = TCOD - COD_S = TCOD_{INF} - COD_{GF,INF} \]
Soluble COD excluding the colloidal is expressed as $\text{COD}_{MF}$ and measured from membrane filtering the COD according to:

$$
\text{COD}_{MF} = S_{BSA} + S_{BSP} + S_{BSC} + S_{US} = \text{COD}_{MF,INF}
$$

(Eq. 6)

The total soluble readily biodegradable COD (the total of acetate, propionate, and complex soluble COD but without slowly colloidal COD) is calculated from the measured micro filtered fraction $\text{COD}_{MF}$ according to:

$$
S_{BS} = S_{BSA} + S_{BSP} + S_{BSC} = \text{COD}_{MF} - S_{US} = \text{COD}_{MF,INF} - \text{COD}_{GF,EFF}
$$

(Eq. 7)

The fraction of soluble readily biodegradable COD is given by:

$$
F_{BS} = \frac{S_{BS}}{TCOD} = \frac{(S_{BSA} + S_{BSP} + S_{BSC})}{TCOD} = \frac{\text{COD}_{MF,INF} - \text{COD}_{GF,EFF}}{TCOD_{INF}}
$$

(Eq. 8)

Influent acetate (+ propionate) is direct measured as VFA:

$$
S_{BSA} + S_{BSP} = VFA_{INF}
$$

(Eq. 9)

The fraction of readily biodegradable COD which is acetate is given by:

$$
F_{AC} = \frac{S_{BSA}}{S_{BS}} = \frac{S_{BSA}}{(S_{BSA} + S_{BSP} + S_{BSC})} = \frac{VFA_{INF}}{\text{COD}_{MF,INF} - \text{COD}_{GF,EFF}}
$$

(Eq. 10)
From the difference between the glass and membrane filtered COD, the colloidal fraction can be calculated according to:

\[ X_{SC} = COD_S - COD_{MF} = COD_{GF,INF} - COD_{MF,INF} \]

(Eq. 11)

The last soluble parameter to be calculated is the complex soluble COD \( S_{BSC} \) calculated from the measurements according to:

\[ S_{BSC} = COD_{MF} - S_{BSA} - S_{BSP} - S_{US} = COD_{MF,INF} - VFA_{INF} - COD_{GF,EFF} \]

(Eq. 12)

The total soluble (readily and slow colloidal) biodegradable COD (\( S_S \)) is the total of acetate, propionate, complex soluble COD and colloidal COD (influent methanol is assumed zero) given by:

\[ S_S = S_{BSA} + S_{BSP} + S_{BSC} + X_{SC} \]

(Eq. 13)

And calculated according to:

\[ S_S = COD_S - S_{US} = COD_{GF,INF} - COD_{GF,EFF} \]

(Eq. 14)

In the figure below biodegradable COD (\( S_S \)) is divided in fractions. BioWin notation of \( S_S \) should not be confused with IAWQ \( S_S \) which equals BioWin \( S_{BS} \).
Figure 34. BioWin wastewater fractions of soluble biodegradable COD (Ss). The fraction is measured by glass filtering and includes all soluble and colloidal material. Blue fractions are soluble and (olive) green fractions (colloidal) particulate.

The last two influent fraction that need to be calculated are related to the solids: particulate biodegradable COD and unbiodegradable COD according to (Eq. 4):

\[ COD_X = X_{SP} + S_{UP} + X_{BH} \approx X_{SP} + S_{UP} \]

These fractions are estimated from the BOD measurements in the influent as explained in the following sections of this chapter.

The BioWin influent tab the fraction of slowly biodegradable influent COD which is particulate is given by:

\[ F_{XPS} = \frac{X_{SP}}{X_{SC} + X_{SP}} \]

(Eq. 15)

VSS is often calculated from ISS (Ash) measurement according to:

\[ VSS = TSS - ISS \]

(Eq. 16)

The influent ratio of particulate (non-colloidal) COD to VSS is given by:

\[ F_{CV} = \frac{COD_X}{VSS} = \frac{TCOD - COD_s}{VSS} = \frac{TCOD_{INF} - COD_{GF,INF}}{TSS - ISS} \]
Ammonia is given by:

\[ NH_3 = F_{NA} \times TKN \]  
(Eq. 18)

Soluble unbiodegradable organic nitrogen is given by:

\[ N_{US} = F_{NUS} \times TKN \]  
(Eq. 19)

Nitrogen from organisms present in the influent is calculated by the sum of the products of the various organism concentrations and their respective nitrogen fractions, i.e.:

\[ Organisms, N = \sum Z_{bx} f_{N,Zbx} \]  
(Eq. 20)

Unbiodegradable particulate nitrogen is given by:

\[ X_{IN} = F_{UP,N} \times F_{UP} \times TCOD \]  
(Eq. 21)

The remaining organic nitrogen is broken into particulate and soluble components. Particulate biodegradable organic nitrogen is given by:

\[ X_{ON} = (TKN - NH_3 - N_{US} - X_{IN} - Organisms, N) \times F_{NOX} \]  
(Eq. 22)

Soluble biodegradable organic nitrogen is given by:

\[ N_{OS} = (TKN - NH_3 - N_{US} - X_{IN} - Organisms, N) \times (1 - F_{NOX}) \]  
(Eq. 23)
Similarly, an explanation of the fractionation of influent phosphorus is as follows. Soluble orthophosphate is given by:

\[ PO_4 = F_{P,04} \times TP \]  
(Eq. 24)

Phosphorus from organisms present in the influent is calculated by the sum of the products of the various organism concentrations and their respective phosphorus fractions, i.e.:

\[ Organisms, P = \sum Z_b x f_{P,Zb} \]  
(Eq. 25)

Unbiodegradable particulate phosphorus is given by:

\[ X_{IN} = F_{UP,P} \times F_{UP} \times TCOD \]  
(Eq. 26)

The remaining particulate biodegradable organic phosphorus is given by:

\[ X_{OP} = TP - PO_4 - X_{IP} - Organisms, P \]  
(Eq. 27)
Appendix 4. Winter 2022 results dynamic model validation

Winter operation process flow diagram

Figure 35. WWTP Poreč-South - BioWin model winter operation. Lines 1 and 2 and MBR’s A and B are in operation (dashed lines not operated).

Average performance overview
Based on the total dataset the average WWTP performance is calculated and presented in the tables below. The effluent performance and aerobic SRT is well within the design criteria. There are no solids measured in the effluent because of the MBR technology. Total nitrogen is well below the effluent standard. Effluent COD is largely inert soluble material.

Table 6. WWTP Poreč-South - Winter 2019 - Dynamic average effluent concentration (mg/L)

Influent modelling results

Figure 36. Winter 2022 - WWTP Poreč-South dynamic model Influent flow.
Figure 37. Winter 2022 - WWTP Poreč-South dynamic influent load COD, TKN and TP.

Process and recycle flows modelling results

Figure 38. Winter 2022 - WWTP Poreč-South flow rate settings and control. The MLSS sludge return flow is proportional to the influent at 1800%. The maximum capacity is 13.670 m³/d per MBR. The WAS flow is operated 10 hours a day on a constant flow to the dewatering.
Figure 39. Winter 2022 - WWTP Poreč-South flow rate settings and control. The bypasses are not used. The upper bound of the anoxic recycle is according to the design. The anoxic recycle is controlled relative to the influent flow.

Waterline operation modelling results

Figure 40. Winter 2022 - WWTP Poreč-South TSS profile in the waterline. TSS in the MBR is controlled on approximately 2.7 gTSS/L by adjusting the WAS flow and SRT. In the winter, the reactor volume relative to the influent loading is very high. This results in low sludge production and a long SRT. The process is therefore operated with a lower TSS concentration during the winter.
Figure 41. Winter 2022 - WWTP Poreč-South ammonium profile in the waterline. The air input of AT-B is controlled based on NH4 measurements. AT-A is unaerated.

Figure 42. Winter 2022 - WWTP Poreč-South nitrate in the anoxic tank.
Waterline concentration profiles modelling results

**Figure 43.** Winter 2022 - WWTP Poreč-South TSS concentration profile over the waterline.

**Figure 44.** Winter 2022 - WWTP Poreč-South NH4 concentration profile over the waterline.
Figure 45. Winter 2022 - WWTP Poreč-South NO3 concentration profile over the waterline.

Figure 46. Winter 2022 - WWTP Poreč-South PO4 concentration profile over the waterline.
Aeration and DO concentration modelling results

**Figure 47.** Winter 2022 - WWTP Poreč-South air input in the different aerated reactors. AT-A is non aerated. AT-B is step controlled on NH4 measurement. Both MBR’s are setpoint controlled on DO.

**Figure 48.** Winter 2022 - WWTP Poreč-South DO concentration gradients. Aeration is controlled in AT-B and both MBR’s. DO is the result of the designed air input.
**pH and alkalinity profiles modelling results**

**Figure 49.** Winter 2022 - WWTP Poreč-South pH profile over the activated sludge reactors. Influent pH is measured continuously and is not limiting.

**Figure 50.** Winter 2022 - WWTP Poreč-South alkalinity profile over the activated sludge reactors. Influent alkalinity is estimated from local drinking water quality measurements at 7.46 mmol/L. Alkalinity is not limiting.
Chemical load and flow modelling results

**Figure 51.** Winter 2022 - WWTP Poreč-South load and flow of Iron and PE. Effluent load proportional iron dosage is required for P-removal with a factor 0.3 m3/kgP. PE is assumed particulate biodegradable COD with a COD/VSS ratio of 1.42 gCOD/gTSS and dosed proportional to the WAS load based on 8 kg PE (dry weight) dosed per 1000 kg WAS (dry weight) flowing in the dewatering.

Sludge line operation modelling results
**Figure 52.** Winter 2022 - WWTP Poreč-South dewatered sludge and centrate flow.

**Figure 53.** Winter 2022 - WWTP Poreč-South dewatered sludge and screening sludge concentration. The design assumes dewatered sludge at 23% dry matter. Simulation is done with a lower percentage. This does not affect the simulation result. Screening is an estimated concentration as the result of the press operation.

**Figure 54.** Winter 2022 - WWTP Poreč-South Centrate load dewatering.
Effluent modelling results

In the figures below the dynamic effluent quality of the plant is presented under winter conditions. The last day included a major rain event. The measurement is coming from the effluent buffer and has a reduced dynamic profile.

Figure 55. Winter 2022 - WWTP Poreč-South dewatered sludge load and compacted screening load. Dewatered sludge is operated 10 hours a day. Screening is produces continuously as a factor of the influent.

Figure 56. Winter 2022 - WWTP Poreč-South Effluent nitrogen concentration. Effluent is measured in the outflow of the large effluent buffer.
**Figure 57.** Winter 2022 - WWTP Poreč-South Effluent phosphorus concentration. Effluent is measured in the outflow of the large effluent buffer.

**Figure 58.** Winter 2022 - WWTP Poreč-South Effluent COD and BOD concentration. Effluent is measured in the outflow of the large effluent buffer.
